

Commutator Lengths of Free Group Orbits and Their Squares

Mukoseev, Lev (School: School 564)

This work is devoted to finding an element in a free group's commutator subgroup such that the commutator length of the square is less than the commutator length. The results obtained allow us to compute couples $(cl(w), cl(w^2))$ for all elements w of fixed lengths in a free group of rank 2. Using our idea of the stable commutator length of elements in one orbit of $F = F(x, y)$ with respect to the action of the automorphism group $Aut(F)$, we have developed an algorithm which calculates the commutator lengths of orbits of a free group as well as the squares which have an element of length $\leq n$.
