Direct Inhibition of NF-kB Subunits by 9-chloro-8-(hexyloxy)-2H-chromeno[2,3-d] pyrimidine-2,4(3H)-dione (IT-848)

Rateshwar, Janice (School: Jericho High School)

Aberrant Nuclear Factor-kappa B (NF-κB) activation is observed in autoimmune, inflammatory, and malignant disorders. Current therapeutics targeting NF-κB inhibit upstream NF-κB activators, allowing for broad-spectrum toxicity and alternative mechanisms of NF-κB activation. To address these limitations, 9-chloro-8-(hexyloxy)-2H-chromeno[2,3-d]pyrimidine-2,4(3H)-dione (IT-848) was developed as a direct NF-κB inhibitor. This study analyzed the unknown molecular mechanisms of action of IT-848 based on molecular docking and gene expression analyses to elucidate the candidacy of IT-848 as a therapeutic for diseases with constitutive NF-κB activation. Molecular docking analysis on PyRx revealed IT-848 demonstrates a strong binding affinity (binding energy <-6 kcal/mol) and non-covalent interactions with amino acid residues in the REL Homology Domain of all NF-κB subunits: RelA, RelB, c-Rel, p50, and p52. Therefore, IT-848 is a competitive and reversible inhibitor of DNA binding for all NF-κB dimers. Using Multiple Myeloma (MM) as proof of concept, differentially expressed genes induced by IT-848 in MM1S MM cell line were identified on BasePair and mapped for overlap on Venny with the target genes of RelA, RelB, c-Rel, p50, and p52 listed in the Harmonizome Database. IT-848 downregulated (log2foldchange <-1.5) target genes of each NF-κB subunit. Thus, IT-848 is a potential therapeutic candidate for disorders with constitutive NF-κB activation by inhibiting various NF-κB-mediated pathways implicated in disease progression in a reversible, and therefore tumor-cell toxicity specific, manner. Further research should investigate IT-848 in autoimmune and inflammatory disorders and test the synergy of IT-848 with other MM therapeutics.
