

# C60 Buckminsterfullerene Derivatives for DNA-Encoded Libraries, Fullerene-Supported Synthesis, and High-Throughput Screening

Phillips, John-Mark (School: Seminole Ridge Community High School)

Buckminsterfullerenes exhibit remarkable reactivity compared to the chemistry of other carbon allotropes due to all double bonds being unconjugated. This leads to it being a super electron deficient polyolefin. It has been reported that C60 undergoes a  $\text{AlCl}_3$  catalyzed pseudo Friedel-Crafts reaction in neat benzene to give a product of fullerenated aromatics corresponding to the formula  $\text{C}_{60}\text{H}_n(\text{C}_6\text{H}_5)_n$ , where  $n$  is predominantly 12. Here is reported the formation of aromatic amine adducts in moderate yield, specifically 3-phenyl-1-propylamine and benzylamine, with C60 under similar conditions. These fullerene derivative shows particular promise for use in modified solid-phase synthesis (SPS) and DNA-encoded libraries (DEL) systems. Here is proposed a new method of integrating the combinatorial solid-phase synthesis of DNA-encoded libraries, the assay of small molecule ligands, and the sequencing of encoding oligonucleotides into one process; with the aid of amine-terminating fullerene derivatives and Illumina dye sequencing.
